

n8n SEO Content Generation Workflow

A practical build plan for moving keyword rows through research, AI content generation, WordPress publishing, and traceable write-back - without duplicate runs or silent failures.

Goal Turn an existing prompt set and spreadsheet into a reliable end-to-end n8n publishing workflow.	Core stack n8n - Google Sheets - OpenAI/API - WordPress REST API	Reliability focus Idempotency, row-level status, post ID/URL write-back, error visibility.
--	--	--

Workflow architecture

How I would structure the n8n build

1. Row gate / duplicate protection	Read only rows that are ready and have no existing WordPress post ID. A processing status is written before the AI steps start, so the same keyword cannot be picked up twice by overlapping runs.
2. Research stage	Pass the row's keyword and any supplied research inputs into the client's existing research prompt. Return a structured result that can be reused downstream rather than one unstructured text blob.
3. Content generation stage	Feed the research output into the existing content prompt and request predictable fields such as title, slug, meta description, article body, and optional excerpt.
4. WordPress publish stage	Send the generated fields through the WordPress REST API. The workflow can create a draft first or publish directly, depending on the chosen safety level.
5. Confirm and write back	Only after WordPress confirms creation, write the post ID, live/draft URL, processed timestamp, and final status back to the same spreadsheet row.

Reliability and handoff details

The workflow is not finished when content is generated. It is finished when every row has a visible state, WordPress confirms what happened, and failures can be retried without creating duplicate posts.

Suggested spreadsheet state

keyword	status	wp_post_id	wp_url	processed_at	error
best crm for real estate	published	1842	/best-crm-real-estate/	2026-09-28 10:14	-
ai lead follow up	error	-	-	-	WP 403 - blocked
n8n seo workflow	ready	-	-	-	-

Example fields only. The exact column names can be mapped to the client's existing sheet rather than forcing a new spreadsheet structure.

Failure handling that prevents messy reruns

WordPress rejects a post	Store the API status/error on that row; do not mark it complete. Retry only the failed row after the access issue is fixed.
AI response is incomplete	Validate required fields before publishing. Missing title/body/meta fields route to an error branch instead of sending broken content to WordPress.
n8n run is triggered twice	Use row status plus WordPress post ID as the idempotency gate so already-created posts are skipped.
Security plugin blocks REST API	Test authentication and the post endpoint first. If blocked, resolve the WordPress/API access path before building the full generation chain.

End-to-end test plan

Test	What I verify
Keyword 1 - normal case	Research -> content -> WordPress -> post ID/URL write-back all complete once.
Keyword 2 - content edge case	Long/complex output preserves headings, links, lists, and article body formatting.
Keyword 3 - failure/retry	A controlled failure is visible in the sheet and can be retried without creating a duplicate post.

What the client receives

n8n workflow	Connected workflow using the client's prompts and spreadsheet structure.
WordPress integration	REST API mapping for title, slug, meta description, article body, and chosen post status.
Visible row tracking	Status, WordPress post ID, URL, processed timestamp, and error feedback.
Testing + handoff	Three end-to-end keyword tests plus a short handoff explaining credentials, editable nodes, and retry behavior.

Scope note: This document is an independent workflow sample prepared to demonstrate the proposed implementation approach. It is not presented as a completed client deployment or as evidence of client results.
